

Calculating Home Protected Loads for Emergency Backup Purposes - Generac PWRcell

There are a few important items to consider when estimating protected loads for your battery energy storage system:

- **Max Running Wattage.** This is the average sustained power that an electrical load consumes while operating.
- **Starting Wattage.** When devices with inductive motors are powered on, they will briefly draw initial current and power (“surge”) that is higher than their Running Wattage. For example, a refrigerator with a compressor will switch its compressor on and off continuously to maintain temperature. The appliance’s “Power/Ratings” will generally include the maximum Starting Wattage information.
- **Run Time.** This is the time that a load is drawing power (powered on).

These wattage worksheet instructions focus on determining your estimated total wattage requirements that prevent or minimize nuisance power trip events during a power outage. Nuisance power tripping occurs when instantaneous power demand exceeds the peak power output capabilities of the energy storage system while in backup mode. Generally, greater battery capacities allow for longer periods of running time during a grid power outage.

Since your home will still be grid-connected with battery backup (and you are not going completely off-grid), it is possible to install a battery that is relatively small and affordable. First, it is necessary to determine what items in the home are most essential to keep powered, when a power outage occurs. The battery system will not be able to provide or sustain all the power needs of your home during a power outage, so it is necessary to plan for the amount of energy that is absolutely necessary during these critical events.

There is a technical limit on the amount of power that can be drawn from battery systems during a grid outage. These ratings are listed in the chart that follows. The length of time that the batteries can supply power to protected loads during an outage is based on the amount of energy being used and how much battery capacity is available.

Generac PWRcell Battery Energy Storage Systems have the following maximum power ratings while in backup mode.

Running Wattage (without optional ATS)	Starting Wattage (2 Secs)	Surge Wattage (30 Mins)
7,600 Watts	11,000 Watts	9,000 Watts

FAQs

Q: Will my entire home be powered during a grid outage?

A: Unfortunately, no. Emergency power is limited to items that are either plugged into or hard wired to the protected loads panel. An Automatic Transfer Switch (ATS) and additional load control devices are necessary for whole home backup.

Q: How many watts does it take to power essential items during a grid outage?

A: In a typical home, essential items will average 3000 – 5000 watts of power to run. To run the entire home will require much more power than is practical for a standby/backup battery energy storage system.

Q: What is the difference between running watts and starting watts?

A: Running, or rated watts are the continuous watts needed to keep items running. Starting watts are extra watts needed for two to three seconds to start induction motor-driven products like a refrigerator or circular saw — this is the maximum wattage the system will be loaded with.

Q: What if I can't determine the running or the starting watt requirement for an appliance?

A: If the running watts are not on the appliance, you may estimate using the following equation: $WATTS = VOLTS \times AMPS$. Only motor driven items will require starting watts. The starting watts required may also be estimated at 1-2x the running/rated watts, but may be as high as 7x.

Q: What happens if I do experience nuisance power tripping?

A: The energy storage system will automatically reset after a short period of time and reattempt to meet the power requirement. You may need to reduce the power requirement by turning off some devices to prevent further power tripping events.

Protected Loads Worksheet Instructions

Choosing items for a backup load circuit and managing its use is a matter of prioritization and budgeting power.

Step 1

Determine the essential items you wish to power simultaneously. It is best to get the information directly from the actual appliance you intend to use, but you can also refer to the following chart to assist in estimating this information. Fill-in the running watt and starting watt requirements on the "Essential Loads Worksheet."

Step 2

For load items that don't have a higher Starting Watts value, use the Running Watts as the Starting Watts value.

Step 3

Add the Starting Watts values for the protected load items you want to power. This will provide the total of these items' peak power requirement, when used simultaneously.

Step 4

Add the Running Watts of the protected load items you wish to power. Enter this number in the Total Running Watts column. This is the sustained power requirement to support all of these devices at one time.

Step 5

Choose the higher of the two values, "Starting Watts" and "Running Watts", and enter it into the box labeled "Minimum Power Requirements". If this value is larger than the "Max Output Wattage", you must remove one or more protected load items.

	Running Wattage	Starting Wattage (3 Secs)	Surge Wattage (30 Mins)
Generac PWRcell Max Ratings	7,600 Watts	11,000 Watts	9,000 Watts

EXAMPLE		
APPLIANCE OR TOOL	Running Watts	Starting Watts
1. Energy Star 25.4 cu. ft. Refrigerator	73	1800
2. Television	500	500
3. Microwave Oven-800 Watts	625	800
4. Incandescent Light Bulb-40 Watt x 4	160	160
5. AM/FM Radio	100	100
6. Security System	500	500
7. Cell Phone Battery Charger x 2	50	50
8. Automatic Washing Machine	1150	2300
